Jingyi Gus

1. a)
$$\int_0^x k\lambda(\lambda t)^{k-1}e^{-(\lambda t)^k}dt$$
 let $y = \lambda t$

$$= \int_0^{x} k y^{k-1} e^{-y^k} dy$$

$$= -e^{-y^k} \int_0^{x}$$

$$= 1 - e^{-(xx)^k}$$

Solve
$$u = F(x) = 1 - e^{-(\lambda x)^k}$$

 $\therefore 1 - u = e^{-(\lambda x)^k}$

$$(-1)^{k} = \ln(1-u)$$

$$(x = \frac{1}{2}(-\ln(1-u))^{\frac{1}{k}} = F^{-1}(u)$$

If $U \sim U(0,1)$, we define $X = \frac{1}{\lambda} [E - |n(1-u)]^{\frac{1}{k}}$ to generate this dist.

b)
$$X = F^{-1}(u) = \inf_{x \in A} \int_{A}^{2x} |u| = 1 - e^{-2x(x-b)/h}$$

Consider $u = 1 - e^{-2x(x-b)/h}$
 $e^{-2x(x-b)/h} \le 1 - u$

Sina
$$\lim_{x\to\infty} F_x(x) = \lim_{x\to\infty} |-e^{-2x(x-6)/h}| = 1$$

we have : $h>0$.

$$e^{-2x(x-b)/h} \le 1-u$$

$$\frac{-2x(x-b)}{h} \le \ln(1-u)$$

$$x^{2}-bx + \frac{h \ln(1-a)}{2} > 0$$

$$\therefore X \leq \frac{b - \sqrt{b^2 - 2h \ln(1-u)}}{2} \text{ or } X \geqslant \frac{b + \sqrt{b^2 - 2h \ln(1-u)}}{2}$$

Since
$$\frac{b-\sqrt{b^2-2h\ln(1-u)}}{2} \le \frac{b}{2} < b \le \max(0,b)$$
, we have $X = F^{-1}(u) = \frac{b+\sqrt{b^2-2h\ln(1-u)}}{2}$

Since $u \in (0, 1)$, |n(1-u) < 0, $\sqrt{b^2 - 2h(n(1-u)} > |b|$, $X > \frac{b+|b|}{2} = max(b,0)$

: If Un U(D,1), we define X = b+ 1/6-2h(nU-w)

c)
$$\int_{-\infty}^{\infty} \frac{1}{\pi} \frac{1}{1+t^2} dt = \frac{1}{\pi} \arctan t \Big|_{-\infty}^{\infty} = \frac{1}{\pi} \arctan x + \frac{1}{2}$$

Solve
$$u = F(x) = \frac{1}{\pi} \arctan x + \frac{1}{2}$$

$$\therefore \pi u = \arctan x + \frac{\pi}{2}$$

$$\therefore x = \tan(\pi u - \frac{\pi}{2}) = -\cot(\pi u)$$

If $U \sim U(0,1)$, we define $X = -\cot(\pi u)$ to generate this dist.

d) i) Solve
$$u = F(x) = \exp(-\exp(-x))$$

$$\ln u = -\exp(-x)$$

$$ln(-lnu) = -x$$

$$\therefore x = -\ln(-\ln u) = F^{-1}(u)$$

: If U~U(0,1), we define X = -ln(-ln(u)) to generate this dist.

ii)
$$P(Mn-an \leq x) = P(Mn \leq x+an) = P((x_1 \leq x+an) \cap \dots \cap (x_n \leq x+an)) = P(x_1 \leq x+an) \cdots P(x_n \leq x+an))$$

$$= \exp(-\exp(-x-an)) \cdots \exp(-x-an))$$

Let
$$exp(-nexp(-x-an)) = exp(-exp(-x))$$
; we have $-nexp(-x-an) = -exp(-x)$

 $\lim_{n\to\infty} -x - a_n = -x$

an= Inn

: Mn - Inn has a standard Gambel dist.

So Mn is increasing in n, but the growth rate is decreasing (since $\frac{d}{dn}(\ln n) = \frac{1}{n}$ is decreasing in n)

Simulation Methods for Option Pricing

Comment on the quality of methods:

Based on Q-Q plots, we can see that: for 100 observations, the "poor man's" generator does not work very well since the many points (esp. the tails) do not align with the 45 degree line. But for 1000 and 10000 observations, the performance of "poor man's" generator is acceptable.
